

## Assignment 7

The implicit scheme was implemented for the American put option using the forward moving method.

### American put plot:

The plot for the American put is as below

$S_{\max} = 450$

$T = 1$  year

$M = 6000$

$N = 1000$

$dx = 0.0075$

$dt = 0.001$

Along the x axis we have the time, y axis the stock price and the option price along the z axis.

## **Free Boundary:**

The plot for the free boundary is as below:

$S_{\max} = 450$

$T = 1$  year

$M = 6000$

$N = 1000$

$dx = 0.0075$

$dt = 0.001$

Below the boundary is the exercise region and above the boundary we have the holding region.  
Time varies along the x axis and stock price varies along the y axis.

## Test for convergence:

By keeping the  $\Delta x$  constant,  $\Delta t$  was varied and the error was computed by comparing with the reference value for  $\Delta x = 0.0075$  and  $\Delta t = 0.001$ . The error was plotted and it was seen that error is linear in nature as expected.

### **$\Delta t$ convergence:**

By keeping the  $\Delta t$  constant,  $\Delta x$  was varied and the error was computed by comparing with the reference value for  $\Delta x = 0.0075$  and  $\Delta t = 0.001$ . The error was plotted and it was seen that error is quadratic in nature as expected.

### **$\Delta x$ convergence:**

## **Conclusion:**

It was observed that as we refine the mesh grid more accurate results are obtained. Also, there's some instability for certain values for  $dx$  and  $dt$  which can be eliminated using some other finite difference method such as the Crank Nicholson Method.
